GROUND-WATER RESOURCES OF WEST-CENTRAL INDIANA

Preliminary Report: Greene County

By F. A. Watkins, Jr. and D. G. Jordan

ABSTRACT

Greene County in west-central Indiana has an area of about 549 square miles. Consolidated rocks of Mississippian and Pennsylvanian ages and unconsolidated rocks of Pleistocene age are the sources of ground water for domestic, stock, industrial and public supplies. Most of the industrial wells and all of the municipal supply wells tap rocks of Pleistocene age. Wells in the consolidated rocks range in depth from about 40 to about 390 feet and those in the unconsolidated deposits range in depth from about 20 to about 200 feet. The ground waters differ greatly in chemical quality, and field chemical analyses show that locally the iron, sulfate, or chloride content exceeds the recommended standards of the U. S. Public Health Service (1946) for drinking water. Hardness of ground water ranges from soft to very hard in Greene County.

This preliminary report contains tabulated records of about 570 wells and test holes giving information about well construction, water levels, conditions of occurrence, and characteristics of the water-bearing material; selected logs for about 425 wells and test holes giving the driller's description of the material encountered, and a tentative interpretation of their geologic age by the authors; records of 20 springs giving information about geologic source, yield, and temperature of the water; results of 276 field chemical analyses of water from wells, 20 field chemical analyses from springs, and 38 field chemical analyses from streams giving the hardness and the carbonate, bicarbonate, chloride, iron, and sulfate content; and water levels in 3 observation wells indicating the magnitude of short and long-term water-level fluctuations in the unconsolidated rocks. These basic data form much of the material to be used in an interpretive report on the ground-water resources and geology of the area.

A base map of Greene County shows the location of all water wells, springs, oil wells, test holes, drain holes, or holes drilled for purposes other than water supply, and stream sampling sites listed in this report. Additional maps show the availability of ground water and generalized quality of water with respect to hardness and an area of high chloride content.

INTRODUCTION

Purpose and Scope

An investigation of the ground-water resources and geology of nine counties in west-central Indiana has been conducted intermittently since 1950. In 1956 the investigation was placed on a full-time basis and another county was added to the area of study. This investigation is being made by the U. S. Geological Survey in cooperation with the Division of Water Resources, Indiana Department of Conservation, as a part of a broad program of these agencies to inventory and evaluate the ground-water resources of Indiana.

This report is the first of a series of preliminary reports to be published on the ground-water resources and geology of west-central Indiana. The purpose of this report is to make the basic data collected during the investigation available to the public, and to provide a preliminary evaluation of the ground-water conditions and geology as an aid to the development of the ground-water resources. A more detailed and comprehensive analysis will be published in an interpretive report on the ground-water resources and geology of the area.

The investigation was made under the general direction of A. N. Sayre and P. E. LaMoreaux, successive Chiefs of the Ground Water Branch of the Geological Survey and under the immediate supervision of F. H. Klaer, former District Geologist, and C. M. Roberts, District Geologist of the Ground Water Branch for Indiana.

Location and Areal Extent

Greene County is located in the west-central portion of Indiana (fig. 1). The county is rectangular in shape and contains about 549 square miles. It is bounded on the north by Clay and Owen Counties, on the east by Lawrence and Monroe Counties, and on the south by Daviess, Knox, and Martin Counties, and on the west by Sullivan County.

EXPLANATION

AREA COVERED BY THIS REPORT.

AREAS UNDER INVESTIGATION.

AREAS COVERED BY REPORTS PUBLISHED
UNDER THE COOPERATIVE PROGRAM.

SEE PAGE 253 FOR LIST OF PUBLISHED REPORTS.

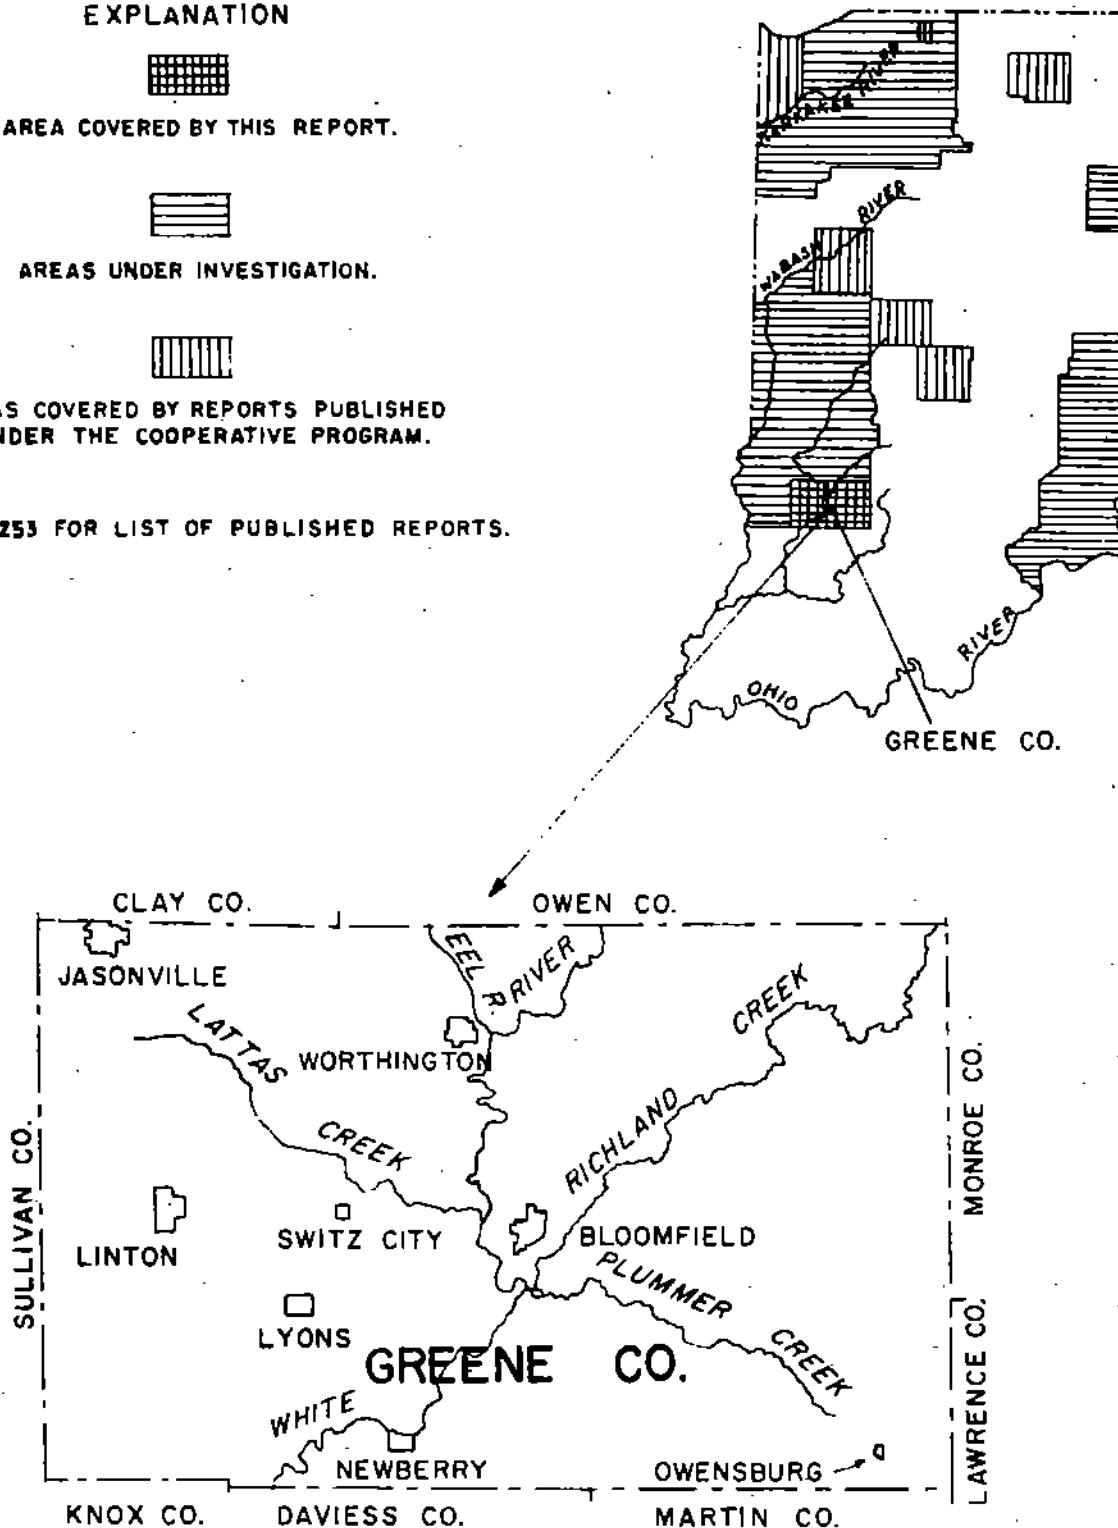

FIGURE 1.-- Map of Indiana showing area covered by this report, areas under investigation, and areas covered by reports published under the cooperative program.

Well-Numbering System

A numbering system is used to locate and identify the wells, test holes, and springs in this report. The number assigned to the well, test hole, or spring indicates its location according to the official rectangular survey of public lands. For example, in the number for well 7/5W-32Pl, the part preceding the hyphen indicates that the well is in T. 7 N., R. 5 W. The first number after the hyphen indicates the section in which the well is located. Each quarter-quarter section (40-acre tract) within a section is given a letter symbol as shown in figure 2. Within the quarter-quarter section, wells are numbered serially. Therefore, well 7/5W-32Pl is the first well listed in SE $\frac{1}{4}$ SW $\frac{1}{4}$ sec. 32, T. 7 N., R. 5 W.

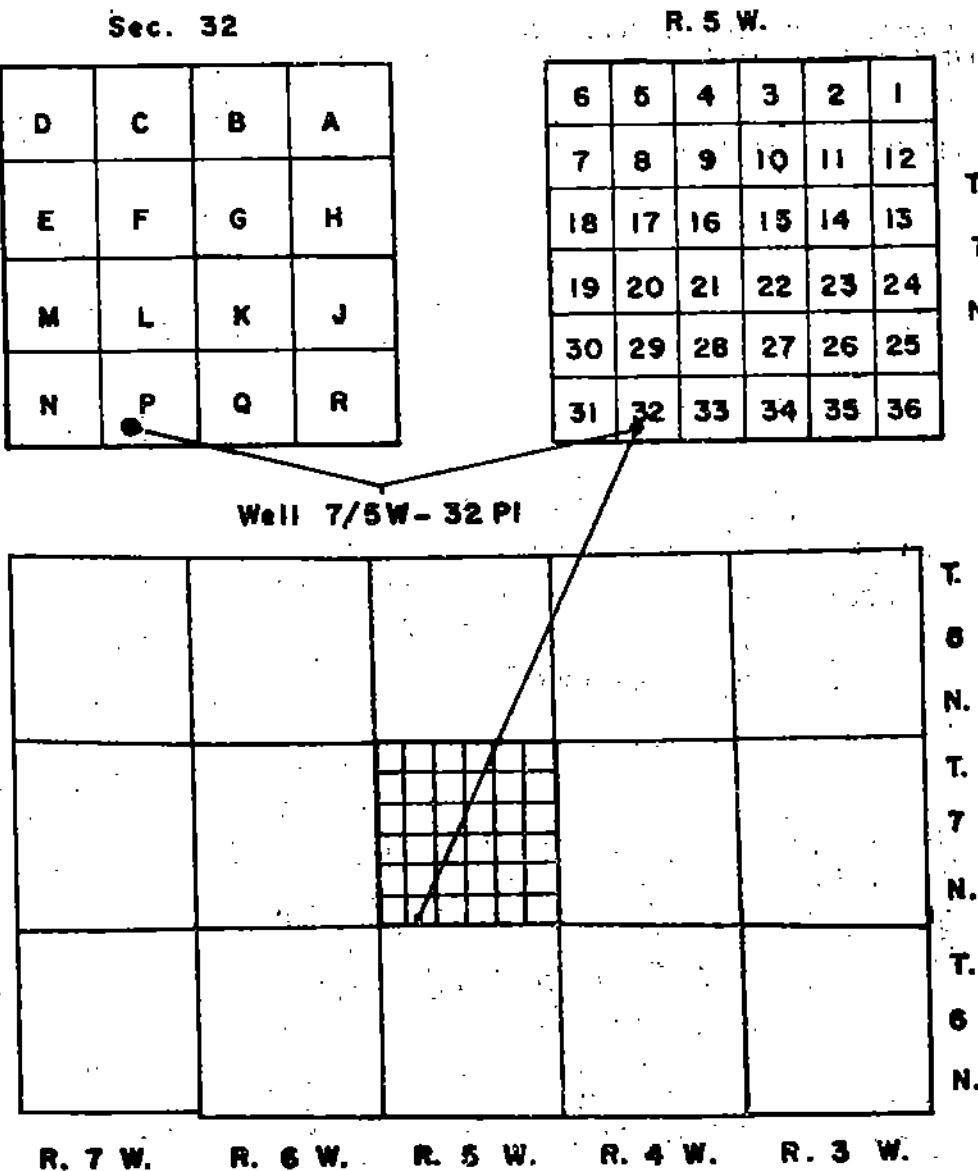

FIGURE 2.--Sketch showing well-numbering system

Acknowledgments

The authors thank all persons who contributed time, information, and assistance during the collection, tabulation, and processing of data for this report. We especially thank the well drillers listed in the table of well records who furnished much of the information summarized in tables 1 and 2.

The authors also thank the following government agencies which provided information for the report: Division of Oil and Gas, and Division of Water Resources, Indiana Department of Conservation.

DATA COLLECTION AND PROCESSING

The well data were collected from drillers, water works superintendents, and others. The well records obtained from drillers were of two types--written records and reports from memory. A tentative driller's location of the well record was obtained at the time of collection and this was checked against the property records in the county courthouse to verify the location, to locate the property, and to obtain the name of the current property owner. Discrepancies between the driller's location and the location shown in the plat books were corrected. The well location was then checked in the field and its location plotted on the appropriate U. S. Geological Survey $7\frac{1}{2}$ minute topographic quadrangle map. The locations given on the records of test holes, oil or gas exploration holes, and wells from other reports were accepted without further verification.

Plate 1 shows the location of water wells, springs, oil wells, test holes, drain holes, or holes drilled for purposes other than water supply, and stream sampling sites. All locations are accurate to the nearest quarter-quarter section and most locations are shown to the nearest quarter-quarter-quarter section (10 acres). The basic data for these wells and holes drilled for purposes other than water supply are summarized in table 1. Selected driller's logs of wells and other drill holes and tentative interpretations by the authors of the geologic age of the material encountered are given in table 2. Basic data for the springs are summarized in table 4.

Samples of water were collected at the time the well and spring sites were visited and from the streams during a period of low flow. These water samples were analyzed in the field office for hardness, alkalinity, and chloride content by standard titration methods. Sulfate was determined by a turbidimetric method using a colorimeter when concentrations were below 100 parts per million and by a standard titration method when concentrations exceeded 100 parts per million. The alkalinity is expressed as carbonate and bicarbonate. The total iron content was determined at the well site by the bipyridine method by comparison with standard color ampules having known iron concentrations. The results of the field chemical analyses (tables 3, 4, and 5) were used to select sites for collecting larger water samples for more comprehensive and accurate analyses by the laboratory of the U. S. Geological Survey.

During the investigation observation wells were established to measure the fluctuations of water level. Table 6 contains water levels obtained from these wells. Data from these wells show seasonal and longer term variations of the ground-water levels.

GEOLOGIC SOURCES OF GROUND WATER

The oldest consolidated rocks underlying Greene County that are important as ground-water sources are of Middle and Late Mississippian and Early and Middle Pennsylvanian age. The rocks of Middle Mississippian age are predominantly limestone whereas those of Late Mississippian age are composed of alternating beds of sandstone, shale, and limestone, in which sandstone and shale predominate. The rocks of Early and Middle Pennsylvanian age consist chiefly of sandstone, sandy shale, and shale. Limestone and coal make up a minor part of the rock units in this sequence. The limestone is of little economic importance but the coal is of major economic importance although it makes up but a small percent of the rocks of Pennsylvanian age.

The rocks of Mississippian age crop out in the eastern one-third of the county. The limestones and sandstones are the chief bedrock source of ground water in this area, the limestones being the more important water-bearing beds. Both the limestones and the sandstones are tapped extensively for domestic and stock supplies.

Rocks of Pennsylvanian age crop out in the remainder of the county and overlie rocks of Mississippian age. Sandstones of Pennsylvanian age are the principal source of ground water from consolidated rocks in the western two-thirds of the county. This source is used extensively for domestic and stock supplies and a few small industrial supplies.

The unconsolidated glacial deposits of Pleistocene age cover slightly more than three-fourths of the county and overlie the consolidated rocks of Mississippian and Pennsylvanian age. Only the southeastern corner of the county is not mantled by glacial deposits. In the upland areas the glacial deposits consist chiefly of a clayey to sandy-clay till. Along the White River and some of its tributaries are extensive deposits of glaciofluvial sand and gravel. These deposits are a major source of ground water for domestic, stock, and industrial supplies and are the only source used for public supplies by the towns and cities in the county. Glaciofluvial sand and gravel deposits in the glaciated area east of the White River are utilized for a small number of domestic supplies.

Lake sediments cover a large part of central Greene County, as shown on plate 2. These lacustrine deposits consist chiefly of silt and clay containing some interbedded sand and gravel lenses. Lacustrine deposits found in the preglacial valley of the White River and its tributaries were either deposited on bedrock or on glaciofluvial sand and gravel. The lake sediments do not yield water freely, but in areas where interbedded sand and gravel lenses are present they may be potential sources for domestic and stock supplies.

To the east, in the unglaciated portion of the county, silt, clay, and sand were deposited in lakes formed by the damming of westward flowing streams by a moraine. The majority of these lake deposits, now above the floors of the present valleys, are not water-bearing. However, in a few areas where these deposits contain water-bearing sand lenses some domestic and stock supplies may be obtained from properly constructed wells.

Rocks of Recent age in Greene County are thin and consist mostly of flood-plain deposits and wind-blown sand. These deposits are not important as sources of ground water.

In Greene County ground water occurs in the consolidated and unconsolidated rocks chiefly under confined (artesian) conditions, but in a few places it occurs under unconfined (water-table) conditions. Under confined conditions, the saturated water-bearing material (aquifer) is overlain directly by relatively impervious material and the water in the well bore will rise above the bottom of the impervious material. Under unconfined conditions the water-bearing material (aquifer) is overlain directly by permeable unsaturated material and the water does not rise above the level at which it is encountered.

Plate 2 shows the availability of ground water in the consolidated and unconsolidated rocks underlying the county. Plate 3 shows the distribution of hardness of the ground waters of Greene County and also shows an area where water is of high chloride content.

TYPES OF WELLS

Drilled wells are the principal type of water wells used in Greene County. However, a small number of driven and dug wells are still in use and occasionally a well is constructed by one of these methods. A few wells have been drilled by the rotary or reverse-rotary methods. Most water wells are 6-inches or more in diameter and are constructed by the cable-tool or percussion method of drilling. A well drilled by the cable-tool method is constructed by a combination of drilling, bailing, and driving casing. When the water-bearing material is consolidated rock, the well casing is generally driven a few inches to several feet into the rock, and the well is finished as an open hole in rock. When the water-bearing material is sand and gravel, the well casing is driven into the water-bearing zone and either left as an open end casing; or the lower end of the casing is slotted or perforated and driven into the water-bearing zone; or a well screen is set opposite the water-bearing zone below the end of the casing. A modification of the above type, the gravel-packed well, has a gravel lining between the well screen and the water-bearing material. In Greene County only municipal supply wells are equipped with well screens. Most domestic and stock wells tapping sand and gravel do not use a screen but are finished with an open end casing or slotted or perforated casing. Greater dependability and improved yield of wells in the coarser unconsolidated materials and development of wells in finer unconsolidated materials is possible with the construction and use of properly screened wells.

In areas where the water level in the unconsolidated material is close to the surface, some water wells are constructed by driving or digging. The driven well consists of a small diameter pipe with a drive point on the end, which is driven into shallow water-bearing material. The dug well is constructed by digging a hole, usually about three feet in diameter, into the upper part of the water-bearing material and using concrete pipe, tile, brick, or stone as a casing.

Oil or gas tests, test holes, drain holes, and holes drilled for purposes other than water supply are generally drilled by the cable tool method in Greene County.

SUMMARY

Preliminary evaluation of the basic data shows that adequate quantities of ground water generally are available for domestic, stock, and in some places for small industrial and small public supplies from the rocks of Mississippian and Pennsylvanian age. In the sand and gravel of Pleistocene age, along the White River and some of its major tributaries, ground water is available in adequate quantities for domestic, stock, and locally for industrial and public supplies. These sand and gravel deposits are the source of all public supplies used by the towns and cities in Greene County. There are deposits of glacio-fluvial sand and gravel east of the White River that are not along the river or its major tributaries. These deposits are used by a small number of domestic wells and should yield adequate amounts of ground water for domestic and stock supplies. Some interbedded sand and gravel is found in the lake sediments on both sides of the White River that contains ground water in adequate quantities for domestic and stock supplies.

The quality of the water from the rocks of Mississippian, Pennsylvanian, and Pleistocene age varies greatly. Locally water from these sources exceeds the U. S. Public Health Service (1946) drinking-water standards for iron, chloride, and sulfate content.

RECORDS

The records of about 570 water wells and holes drilled for purposes other than water are given in table 1. The table contains information about well construction, water levels, yields and drawdowns, thickness and characteristics of the water-bearing material, conditions of occurrence, use, and other data. The altitude of the land surface at all wells (except oil or gas tests) was interpolated from topographic maps. Altitudes of oil or gas test holes were on the records when received and were checked against the topographic maps.

Table 2 contains the selected logs of about 425 wells and other drilled holes. This table gives the drillers' description of the material encountered, pertinent remarks with regard to the material, and tentative interpretation by the authors of the geologic age of the material. The logs contain local terms used by drillers in describing the material penetrated. The most used term "slate" refers to a hard, usually black, fissile shale. The term "boots" is applied to any material, usually a shale, that is sticky and adheres to the bit and stem of the drilling tools. Carbonaceous shale or a slightly shaly coal is called "blackjack". "Iron band" refers to a hard, black to brown iron silicate or iron carbonate rock which occurs as a zone of concretions from pebble to boulder size or in thin beds. An iron band is seldom more than 2 feet thick. The term "steel band" is used for what is reported to be a tan to brown dolomitic fresh-water limestone. "Shells" or "shelly" is used to designate marine fossils in a rock. A dark-gray, sandy shale associated with one of the Pennsylvanian coals is known as the "dirty band".

The results of 276 field chemical analyses of well waters are given in table 3. These analyses were made in the field office of the Geological Survey. Table 3 gives information about geologic source, temperature, concentration in ppm (parts per million) of iron, carbonate, bicarbonate, sulfate, chloride, and hardness of water. The U. S. Public Health Service (1946) drinking-water standards state that the chemical constituents should not exceed the following concentrations: iron and manganese (together), 0.3 ppm; sulfate, 250 ppm; chloride 250 ppm. No standards have been established for hardness of water; however, the following classification is generally used: 0-60 ppm, soft; 61-120 ppm, moderately hard; 121-200 ppm, hard; more than 200 ppm, very hard. Water having a hardness of more than 200 ppm requires softening for most purposes.

The records of 20 springs are given in table 4. This table gives information about geologic sources, yield, use, temperature of the water, and the results of field chemical analyses.

Table 5 gives the results of 38 field chemical analyses of water from streams in Greene County with other pertinent data.

Water levels in 3 observation wells in Greene County are given in table 6. The water levels in two of these wells were obtained by recording gages and in the other well by measurements made with an engineer's steel tape. Daily high water levels are given for observation wells equipped with recording gages and periodic water levels are given for the observation well measured manually. The locations of these observation wells are shown on plate 1.

Sample from up-
per aquifer.

Table 4.--Records of springs, Greene County, Indiana

Spring number: See text for description of well-numbering system.
 Altitude: Altitude of land-surface datum from topographic map.
 Water-bearing material: Ls, limestone; Sa, sandstone; T, till.
 Geologic age: Pl, Paleocene; P, Eocene; M, Mississippian.

Flow: C, estimated; M, measured.
 Use: D, domestic; N, not used; P, public supply; S, stock.
 Field chemical analyses: In parts per million; water samples
 collected on date of measurement.

| Spring No. | Owner | Poplar name | Geologic age | Water-bearing material | Altitude (feet) | Depth (feet) | Date of measurement | Field chemical analyses | | | | | Remarks | | | |

Table 6.--Water levels in observation wells, Greene County, Indiana
 (In feet below land-surface datum, except as noted.
 Water level: e, estimated; h, tape measurement in recorder well)

Greene 1. (6/6W-4B2). Bert Edwards. NW $\frac{1}{4}$ NE $\frac{1}{4}$ sec. 4, T. 6 N., R. 6 W. Dug well, used some for domestic supply, in glacial till, diameter 36 inches, depth 22 feet. Land-surface datum is about 510 feet above msl. Highest water level is 0.87 below lsd, Apr. 10, 1944; lowest is 9.57 below lsd, Dec. 18, 1944. Records available: 1944-45.

Table 6.--Water levels in observation wells, Greene County, Indiana--Continued

Greene 3. (7/6W-20N2). City of Linton. SW $\frac{1}{4}$ SW $\frac{1}{4}$ sec. 20, T. 7 N., R. 6 W. Drilled unused artesian well in glaciofluvial sand and gravel, diameter 8 inches, depth 48.5 feet. Land-surface datum is 482.2 feet above msl. Recording gage installed Apr. 30, 1946 to Oct. 2, 1946; reestablished Mar. 31, 1959. Highest water level is 0.01 above lsd, Apr. 28, 1959; lowest is 30.38 below lsd, Sept. 23, 1946. Records available 1946, 1959. Shows barometric fluctuation; affected by pumping of nearby wells in 1946.

MAP OF GREENE COUNTY, INDIANA, SHOWING
LOCATION OF WELLS AND SPRINGS

Base modified from Indiana
Department of Conservation,
Geological Survey Base Map
No. 28, Greene County,
March 15, 1953

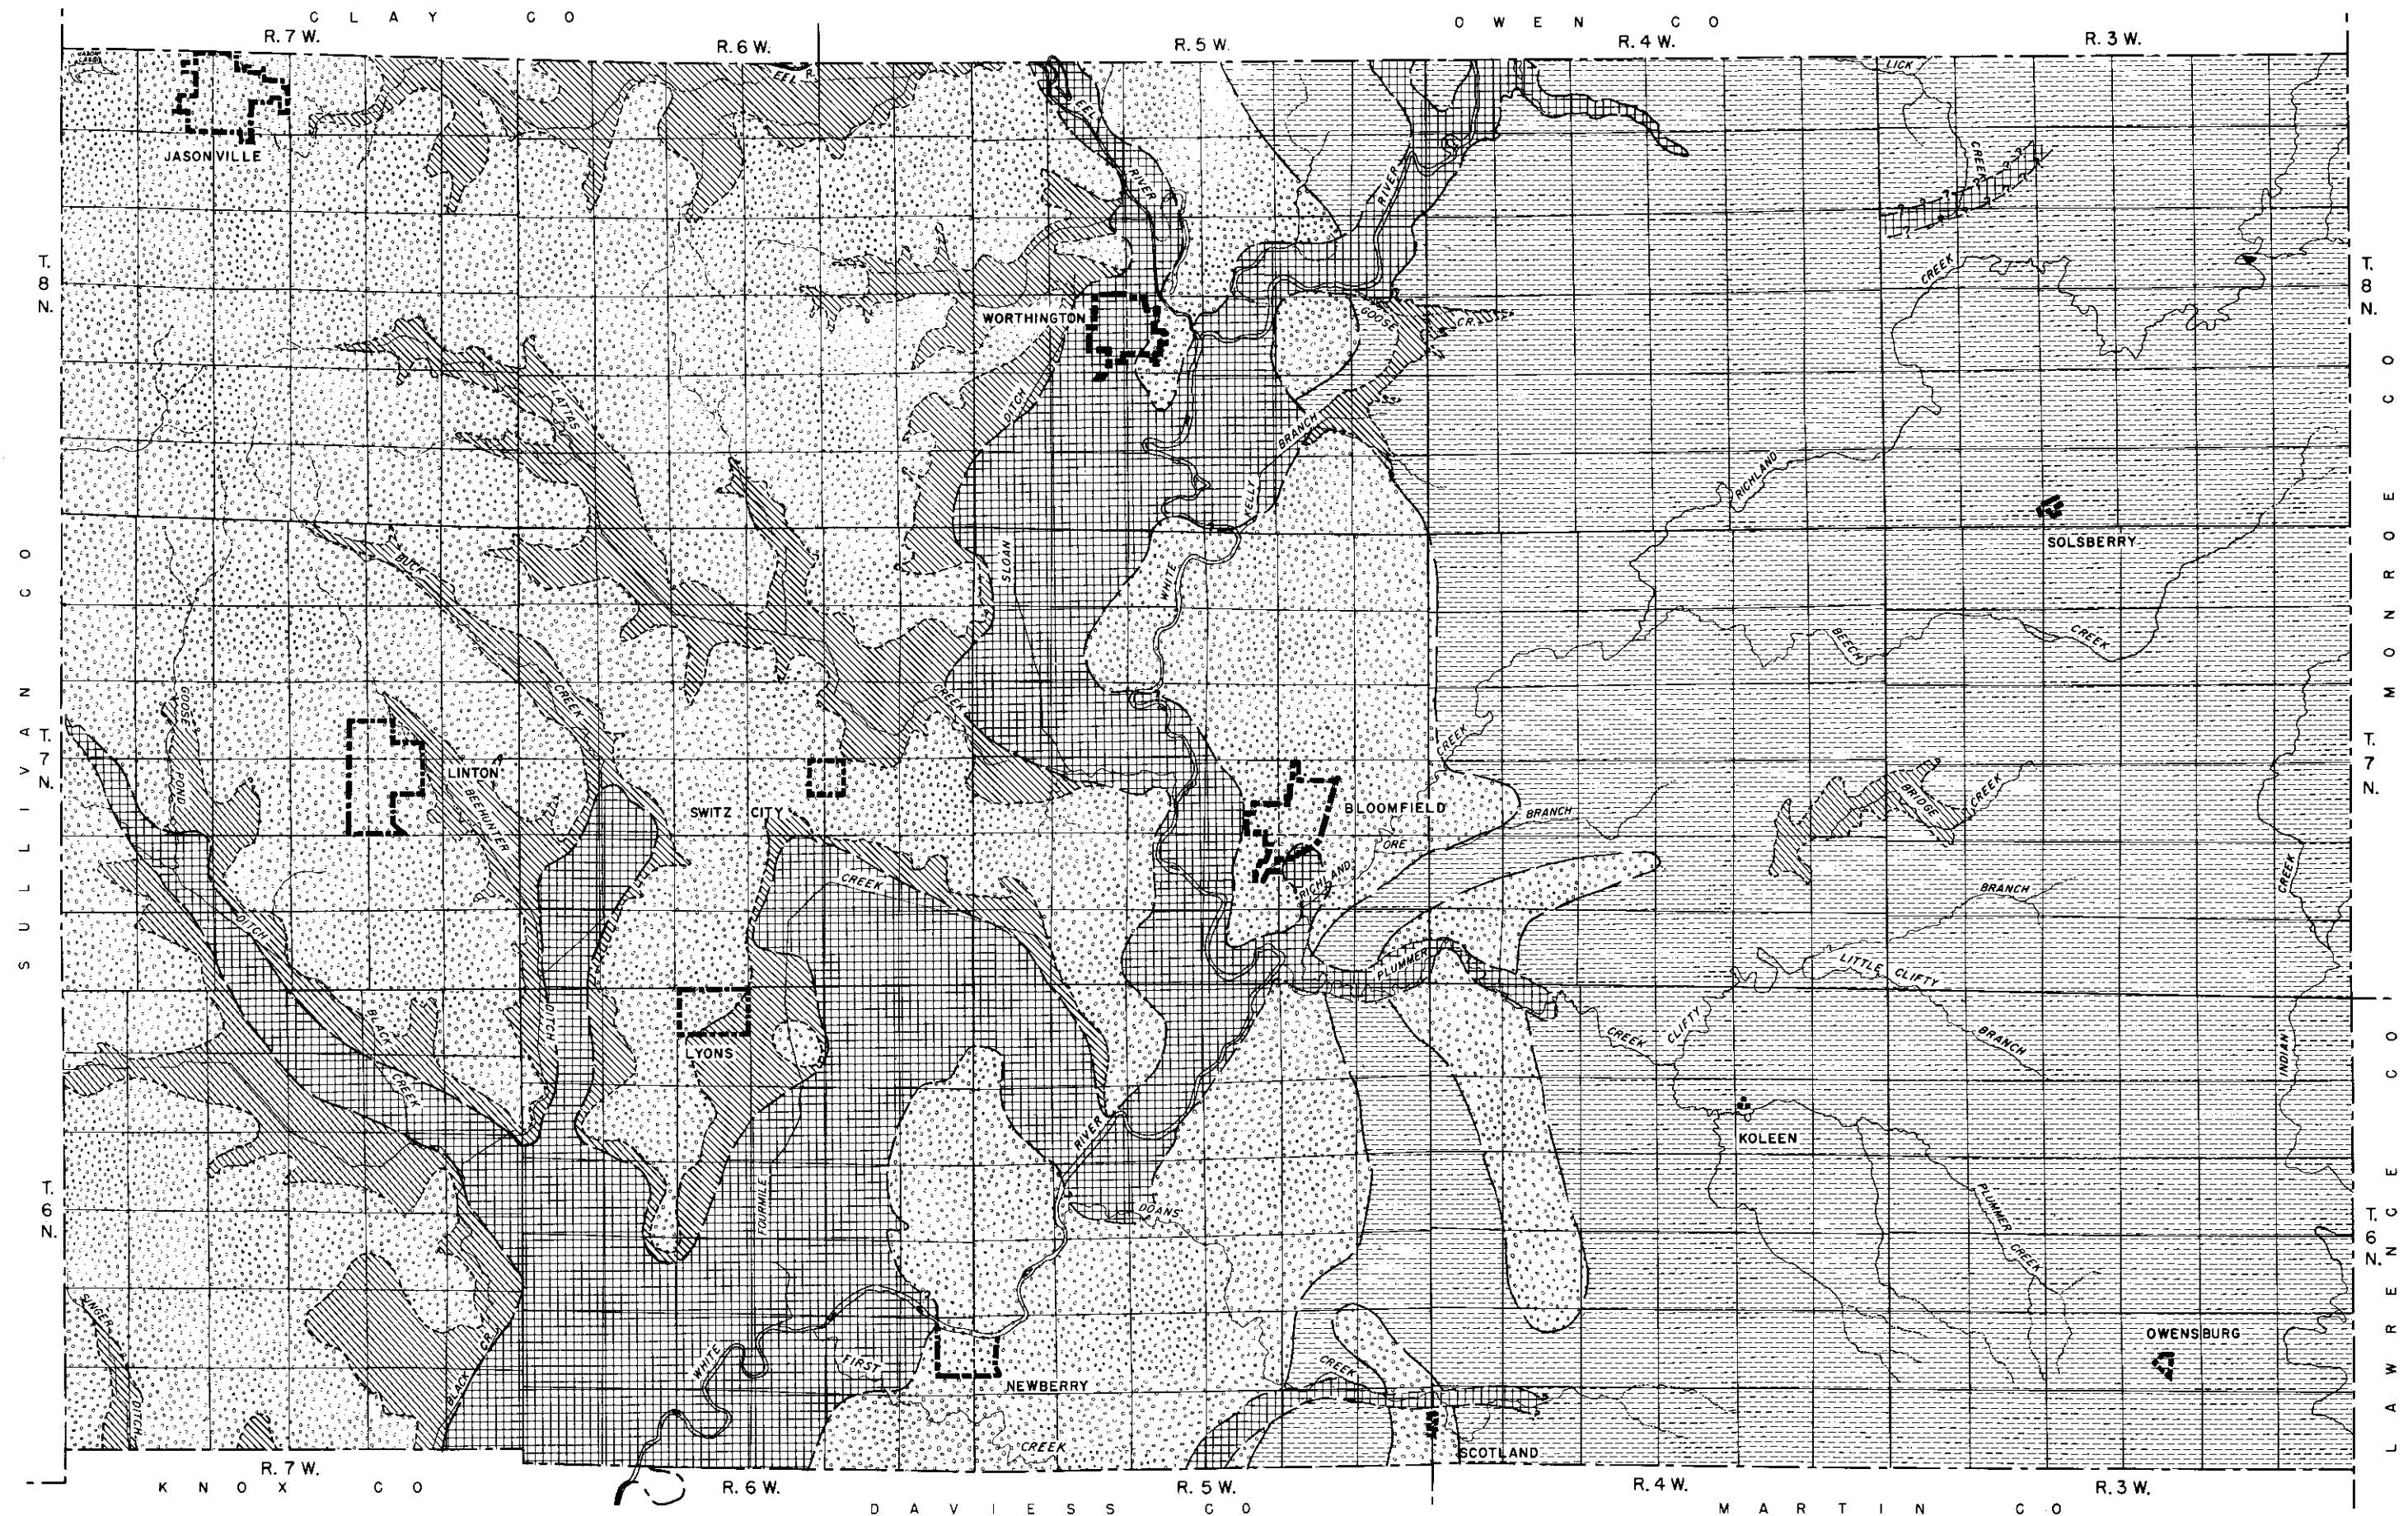

0 1 2 3 4 5 6 MILES
0 5000 10000 15000 20000 FEET
BY F. A. WATKINS, JR. AND D. E. MORRAN
1953

EXPLANATION

- BI Water well
- MI Observation well
- DI Spring
- PI Well for which log is listed in table 2.
- C2 Well or spring for which field chemical analysis is listed in table 2.
- OLE Oil well, test hole, drain hole, or hole drilled for purposes other than water supply.

DIAGRAM OF TOWNSHIP

Base modified from Indiana
Department of Conservation,
Geological Survey, Base Map
No. 28, Greene County,
March 15, 1953

BY F.A. WATKINS, JR. AND D.G. JORDAN
1960

EXPLANATION

Production from sand and gravel

Water from sand and gravel lenses in lake sediments
consisting of clay and silt of pleistocene age. Well
depths range from 20 to 65 feet. Yields from sand
and gravel adequate for domestic and stock use.

Production from bedrock

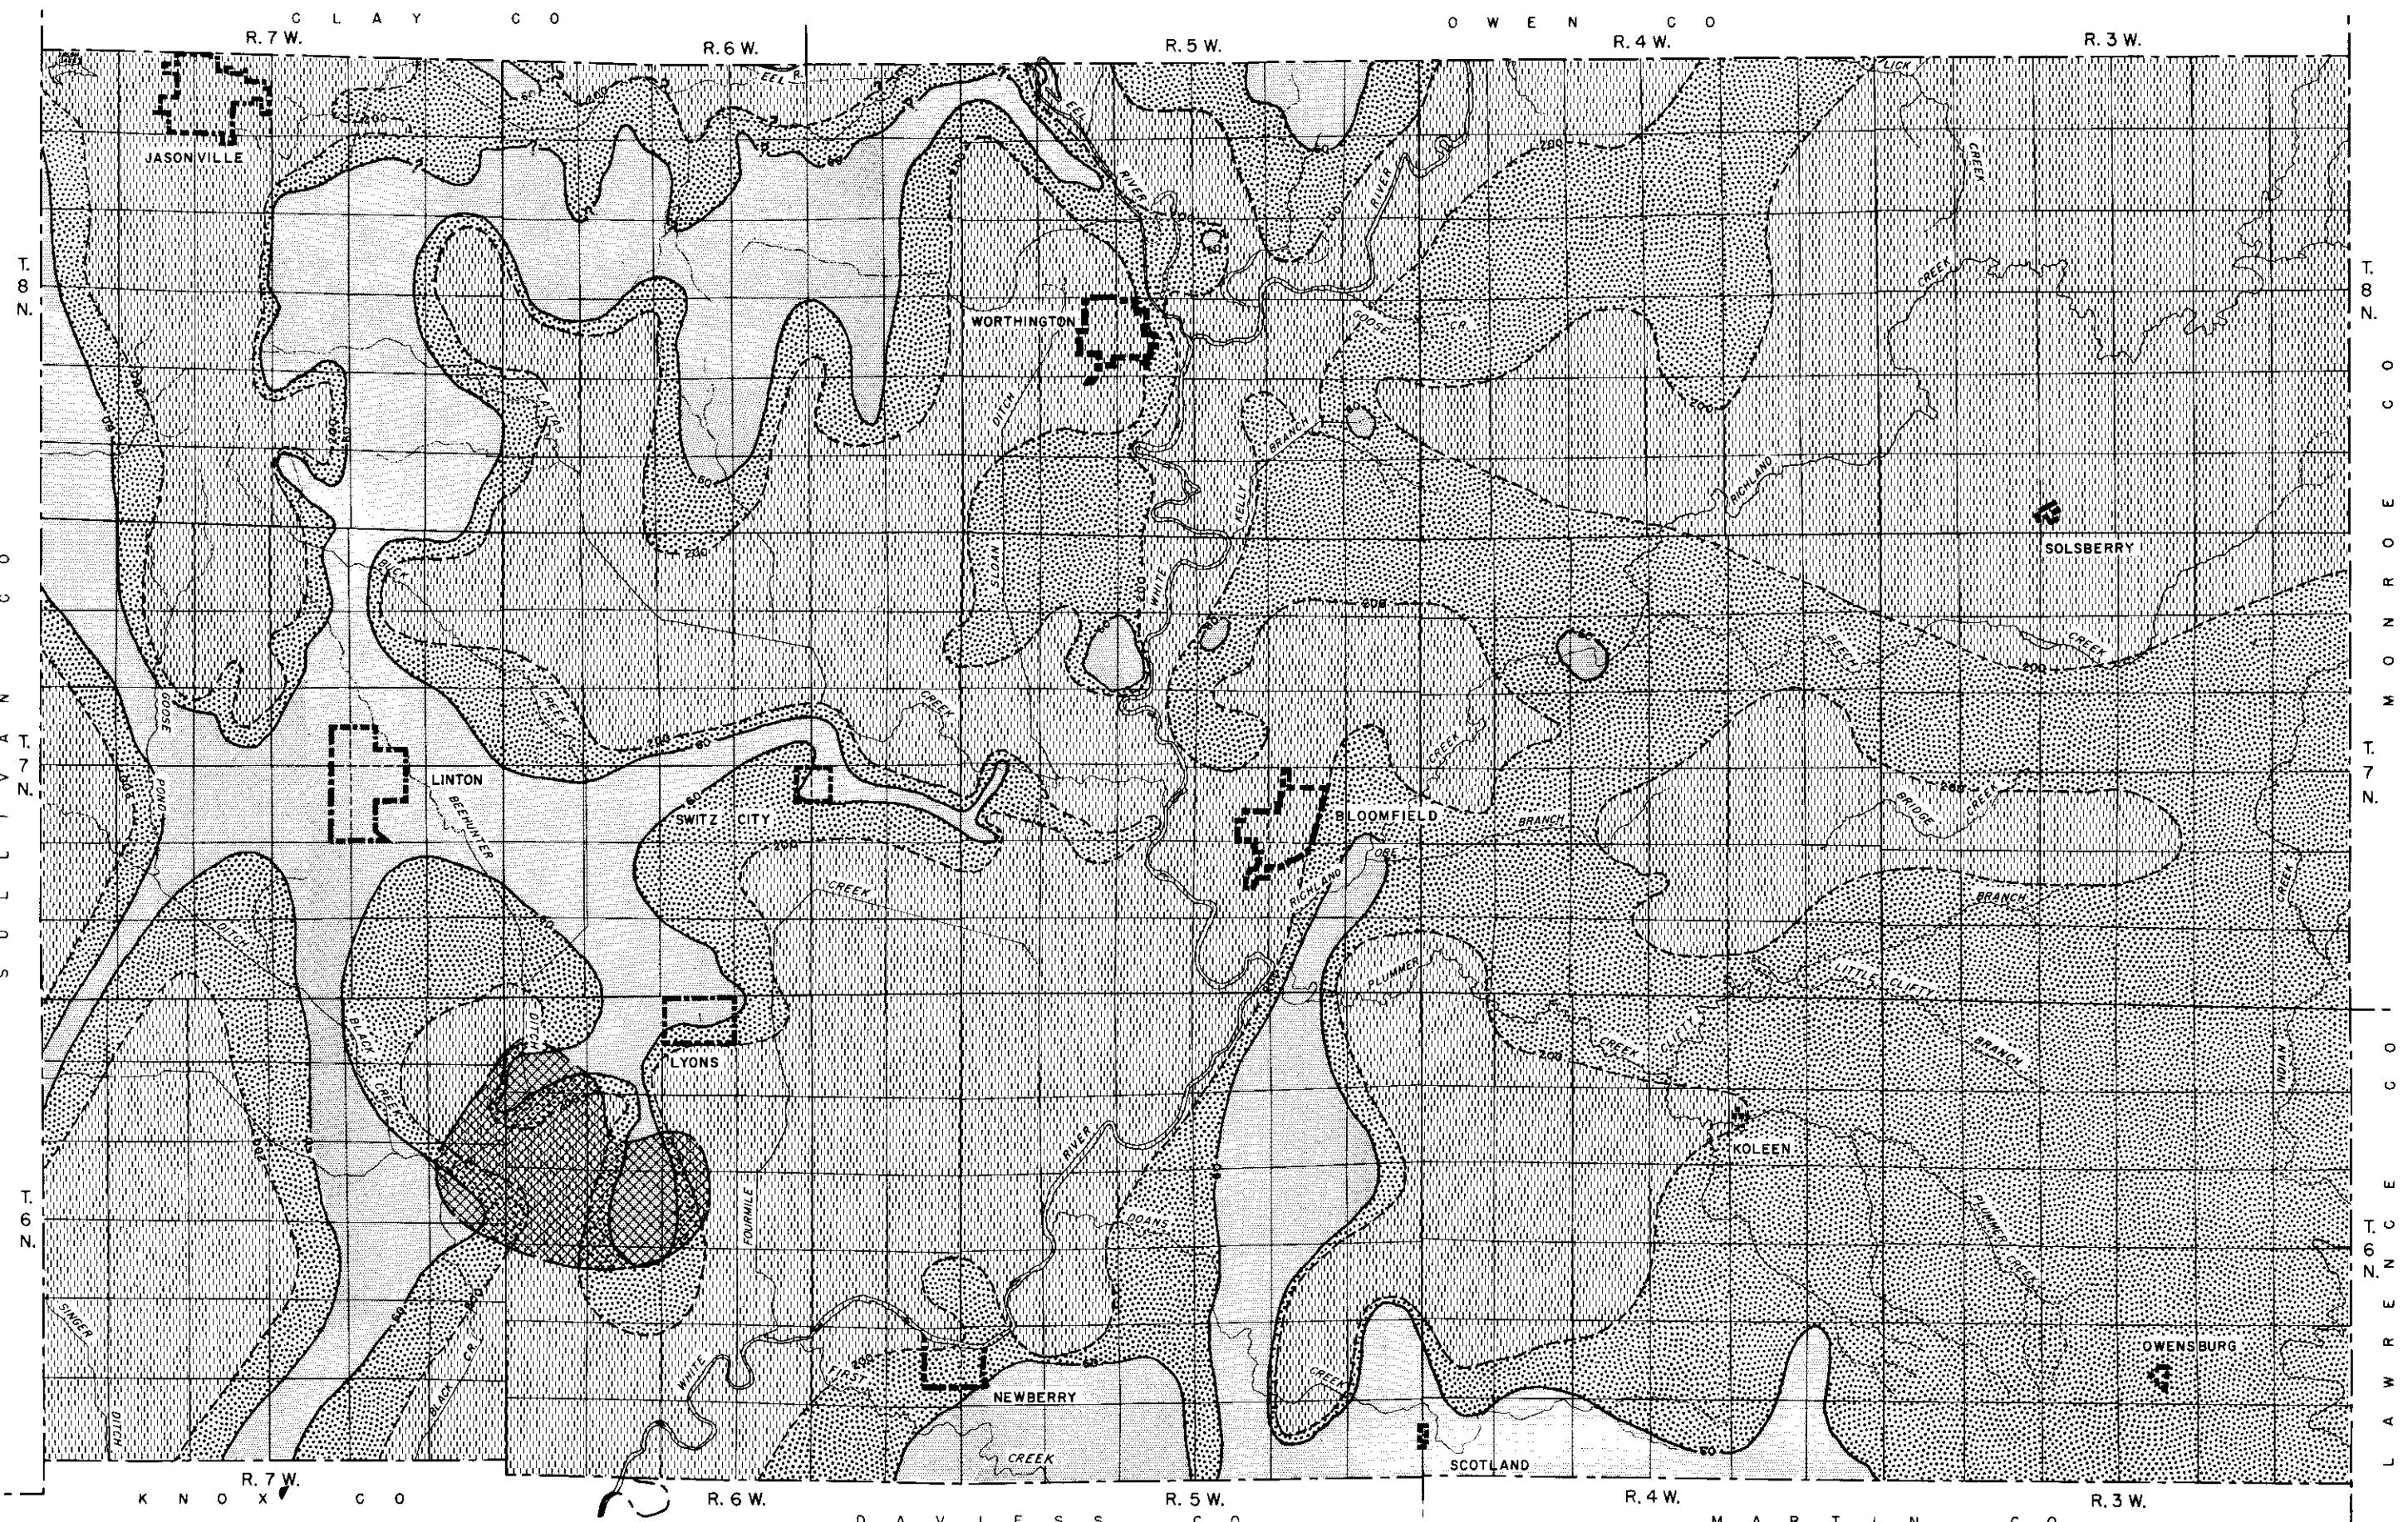

Water predominately from sandstone of Pennsylvanian
age. Well depths range from 40 to 350 feet.
Yields generally adequate for domestic and stock
use.

Water from glaciolacustrine sand and gravel generally
overlain by lake sediments, all of pleistocene age.
Well depths range from 30 to 200 feet. Yields
more than adequate for domestic and stock use.
Some of municipal and industrial purposes and
activities in limestone.

MAP OF GREENE COUNTY, INDIANA, SHOWING
HARDNESS OF GROUND WATER

BY F.A. WATKINS, JR. AND D.G. JORDAN
1960

EXPLANATION

Hardness 0 to 60 ppm.

Hardness 61 to 200 ppm.

Hardness more than 200 ppm.

Area of chloride content in excess of 600 ppm
at depths of 180 feet or less.
